

Cross-Project Piping

By Scott J. Pearson

Configure Cross Project Piping

This module must be enabled on the DESTINATION project. After the module has been enabled the configuration takes place on the individual field level.

There are three action tags that can be configured on the specific fields.

1. **@PROJECTPIPING:** This is the action tag that looks to see what data and where the information is pulled from. Two parameters need to be set up here.
 - Project_id
 - Variable name
 - Example @PROJECTPIPING=[1234][first_name]
 - Note if the project is longitudinal the event must be specified.
@PROJECTPIPING=[123][event_1][first_name]
2. **@FIELDMATCH:** This action tag is what links the project and records together. If record_id is used for both project as your record identifier (first field in the project) then specifying this field in the field match action tag. If the first field is different in the project then you will also need to use the below action tag to specify the source identifier.
 - @FIELDMATCH=record_id
3. **@FIELDMATCHSOURCE:** This action tag will need to specify the source name of the first field in the project if the first field in the source and destination project are not equal.
 - @FIELDMATCHSOURCE=screening_id

Note: For all of these action tags please do not use spaces or quotes.
